Clone, Pull and Commit Inside of IntelliJ IDEA

In this document, I will be guiding you through how to properly clone a repository, pull, and commit all inside of IntelliJ IDEA. No external platform needed. Before you get started it is important to make sure you already have Git installed, if not you can put this address into the search bar https://git-scm.com/install/ and pick your operating system.

Clone / Pull

In order to clone the repository, please follow the instructions provided in “1. Clone The Repository” in the document IntelliJ IDEA Setup Guide provided in the docs/ directory. However, if you have already cloned the repository, and wish to get the latest version of the repository, you will need to first click on the 4 horizontal lines on the top left of the screen, select Git, and then click Pull. For working with the latest approved version you will want to pull from main.

Commit / Push

Once you have completed any changes and wish to move your changes over to the repository there are a few things you must do first. First, you will need to create a new branch with your changes. To do so, you will click on the 4 horizontal lines on the top left corner of the IDE, where you will then select Git, and then New Branch. Once you have given your branch a name, you are ready to first commit. In order to do so, you will go back to the 4 horizontal lines → Git and then Commit. You will type in your commit message which should cover the changes you have made, and then click commit and push.

Congratulations you now understand how to clone, pull, commit, and push to the project!
